## High ABC and OFL...but as always caveats...

- Shift in distribution?
  - Ecosystem survey in Northern Bering Sea this summer found increases in pollock
- Relatively few one-year-old pollock in 2017 trawl survey
- Relatively few old fish in survey (not unexpected)
- Future catches near current levels will require more effort
  - Biomass expected to decline, quite quickly
  - Even higher salmon bycatch?

## Figure added and text edit (page 25)

8. Finally, given the same estimated aggregate fishing effort in 2017, the estimated stock trend is downwards except at low catch levels (a replacement yield of 590 kt is the amount that would maintain the spawning stock constant). Furthermore, the ability to catch the same amount as in 2017 through to 2020 will require about 35% more effort with a decline in spawning biomass of about 28% compared to the current level (based on expected average recruitment).
8. Finally, given the same estimated aggregate fishing effort in 2017, the estimated stock trend is downwards except at low catch levels (a replacement yield of 560 kt is the amount that would maintain the spawning stock constant). Furthermore, the ability to catch the same amount as in 2017 through to 2021 will require about 25% more effort with a decline in spawning biomass of about 20% compared to the current level (based on expected average recruitment; Fig. 41).

## Executive Summary

This is a three species stock assessment for walleye pollock (*Gadus chalcogrammus*), Pacific cod (*Gadus macrocephalus*) and arrowtooth flounder (*Atheresthes stomias*), from the Eastern Bering Sea (EBS), Alaska updated from Holsman et al.(2016). Results are presented from models estimated and projected without trophic interactions (single-species mode, SSM) and with trophic interactions (multi-species mode, MSM).

\* SSB is based on the projected SSB at 2100 (equilibrium)

\*\* Target biomass ratios at year 2100 are based on  $F_{msy}$  proxy of  $B/B_0=0.4$ , given the constraint that  $B/B_0 > 0.35$  for every projection year.
